Tokom istraživanja fokusiranog na sintezu novih kalijumskih silikata elemenata retkih zemalja dobijena su dva jedinjenja do tada nepoznatog hemijskog sastava -  $\text{Cs}_2\text{HoSi}_4\text{O}_{10}\text{F}$  i  $\text{Cs}_2\text{TmSi}_4\text{O}_{10}\text{F}$ , u obliku monokristala.

Jedinjenja su sintetisana metodom rasta kristala iz visokotemperaturnog rastvora ( $T_{\max} = 1373$  K) koristeći  $\text{REE}_2\text{O}_3$  ( $\text{REE} = \text{Ho}, \text{Tm}$ ),  $\text{SiO}_2$  i  $\text{CsF}$  kao polazne suptance. Kristalne strukture oba jedinjenja rešene su iz difrakcionih podataka prikupljenih na odabranim monokristalima. Dobijena jedinjenja su međusobno izostruktturna i kristališu u rombičnoj prostornoj grupi  $Pnma$  sa sledećim parametrima jediničnih celija:  $a = 22,3809(7)$ ,  $b = 8,8686(3)$ ,  $c = 11,9827(4)$  Å,  $V = 2378,41(14)$  Å<sup>3</sup>,  $Z = 8$  (za jedinjenje  $\text{Cs}_2\text{HoSi}_4\text{O}_{10}\text{F}$ ),  $a = 22,3447(5)$ ,  $b = 8,8131(2)$ ,  $c = 11,9594(3)$  Å,  $V = 2355,12(10)$  Å<sup>3</sup>,  $Z = 8$  (za jedinjenje  $\text{Cs}_2\text{TmSi}_4\text{O}_{10}\text{F}$ ). Ispitivana jedinjenja su izostruktturna sa  $\text{Cs}_2\text{YSi}_4\text{O}_{10}\text{F}$  [1] i  $\text{Cs}_2\text{ErSi}_4\text{O}_{10}\text{F}$  [2].

Kristalnu strukturu ovih jedinjenja čine višestruki lanci  $\text{SiO}_4$ -tetraedara koji su povezani beskonačnim jednodimenzionalnim lancima  $\text{REEO}_4\text{F}_2$ -oktaedara. U tunelima koji nastaju kondenzacijom tetraedarske mreže i oktaedarskih lanaca smešteni su kationi cezijuma.  $\text{SiO}_4$ -tetraedri su međusobno povezani preko zajedničkih rogljeva i izgrađuju kolone, odnosno cevastu strukturu.  $\text{REEO}_4\text{F}_2$ -oktaedri međusobno su povezani preko zajedničkih anjona fluora, koji se nalaze u apikalnim rogljevima.

Slika 1. Projekcija strukture  $\text{Cs}_2\text{REESi}_4\text{O}_{10}\text{F}$  paralelna sa pravcem [010] predstavljena poliedrima.

During investigation focused on the synthesis of new potassium rare-earth elements silicates two compounds with a previously unknown chemical composition -  $\text{Cs}_2\text{HoSi}_4\text{O}_{10}\text{F}$  and  $\text{Cs}_2\text{TmSi}_4\text{O}_{10}\text{F}$  were obtained in form of single crystals.

The compounds were synthesized by the method of crystal growth from a high-temperature solution ( $T_{\max} = 1373$  K) using  $\text{REE}_2\text{O}_3$  ( $\text{REE} = \text{Ho, Tm}$ ),  $\text{SiO}_2$  and  $\text{CsF}$  as starting materials. The crystal structures of both compounds were determined by single-crystal X-ray diffraction analysis. They represent mutually isostructural compounds which crystallize in the orthorhombic space group  $Pnma$  with following unit cell parameters:  $a = 22.3809(7)$ ,  $b = 8.8686(3)$ ,  $c = 11.9827(4)$  Å,  $V = 2378.41(14)$  Å<sup>3</sup>,  $Z = 8$  (for  $\text{Cs}_2\text{HoSi}_4\text{O}_{10}\text{F}$  compound),  $a = 22.3447(5)$ ,  $b = 8.8131(2)$ ,  $c = 11.9594(3)$  Å,  $V = 2355.12(10)$  Å<sup>3</sup>,  $Z = 8$  (for  $\text{Cs}_2\text{TmSi}_4\text{O}_{10}\text{F}$  compound). The investigated compounds are isotypic to  $\text{Cs}_2\text{YSi}_4\text{O}_{10}\text{F}$  [1] and  $\text{Cs}_2\text{ErSi}_4\text{O}_{10}\text{F}$  [2].

The crystal structure of these compounds consists of multiple chains of  $\text{SiO}_4$ -tetrahedra connected by infinite one-dimensional chains of  $\text{REEO}_4\text{F}_2$ -octahedra. Cesium cations are located in tunnels formed by condensation of the tetrahedral network and octahedral chains.  $\text{SiO}_4$ -tetrahedra are interconnected through common vertices and form columns, i.e. a tubular structure.  $\text{REEO}_4\text{F}_2$ -octahedra are interconnected via common fluorine apical anions.

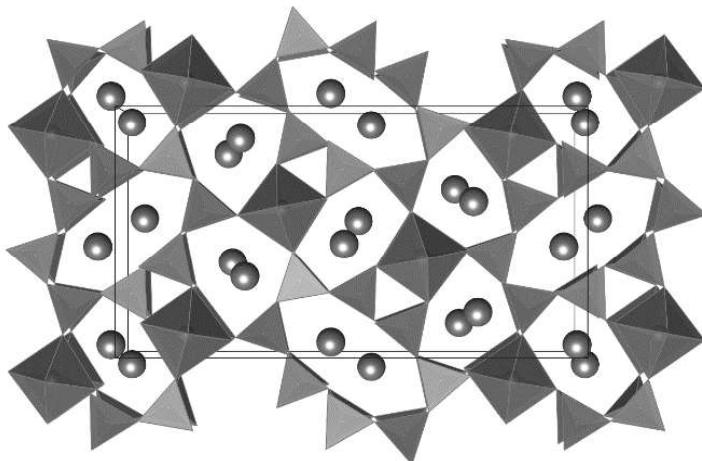

Figure 1. Projection of the structure of  $\text{Cs}_2\text{REESi}_4\text{O}_{10}\text{F}$  parallel to the direction [010] represented by polyhedra.
